21 Declarations of interest: none.

22 **Abstract**

23 Threatening stimuli are thought to induce impulsive responses, but Emotional Go/Nogo task
24 results are not in line with this. We extend previous research by testing effects of task-relevance
25 of emotional stimuli and virtual proximity. Four studies were performed to test this in healthy
26 college students. When emotional stimuli were task-relevant, threat both increased commission
27 errors and decreased RT, but this was not found when emotional stimuli were task-irrelevant.
28 This was found in both between-subject and within-subject designs. These effects were found
29 using a task version with equal go and nogo rates, but not with 90%-10% go-nogo rates.
30 Proximity was found to increase threat-induced speeding, with task-relevant stimuli only,
31 although effects on accuracy were less clear. Threat stimuli can thus induce impulsive
32 responding, but effects depend on features of the task design. The results may be of use in
33 understanding theoretically unexpected results involving threat and impulsivity and designing
34 future studies.

37

38 **1. Introduction**

39 Threat-related stimuli induce tendencies to respond impulsively, in the sense of executing
40 responses when they should be withheld (Hartikainen, Siiskonen, & Ogawa, 2012;
41 Nieuwenhuys, Savelsbergh, & Oudejans, 2012; Schutter, Hofman, & Van Honk, 2008; van Peer,
42 Gladwin, & Nieuwenhuys, 2018; Verbruggen & De Houwer, 2007). Impulsive responding has
43 the advantage of speed, which may be essential, e.g., in life or death situations involving
44 predators, at the cost of reducing the time to complete sophisticated but slow cognitive
45 processing (Cunningham, Zelazo, Packer, & Van Bavel, 2007; Nieuwenhuys & Oudejans, 2012).
46 This may lead to suboptimal choices: For instance, in a simulated shooting situation, increasing
47 the threat associated with the task induced faster shooting and a bias to shoot versus refrain from
48 shooting (Nieuwenhuys et al., 2012). It is therefore important to understand threat-induced
49 impulsivity and the ways we measure it. One measure of impulsive responding is the stop signal
50 reaction time, SSRT (Bari & Robbins, 2013; Verbruggen & Logan, 2008). This is the time
51 required to cancel the execution of a response, when a stop signal is presented after a stimulus
52 initiating a response. As expected, threat has been found to increase the SSRT (van Peer et al.,
53 2018; Verbruggen & De Houwer, 2007), i.e., threat makes it more difficult to inhibit response
54 execution, although this is not always found (Pawliczek et al., 2013; Sagaspe, Schwartz, &
55 Vuilleumier, 2011). Also in line with a shift towards impulsive versus reflective responding, at a
56 neurobiological level threat increases the excitability of the corticospinal tract (Coombes et al.,
57 2009; Schutter et al., 2008) and reduces activity in regions associated with cognitive control
58 (Bishop, 2008; Oei et al., 2012).

59 Of particular interest to the current study, Go-Nogo tasks are frequently used to measure
60 impulsivity. Participants must respond quickly to one stimulus, and to refrain from responding to
61 another stimulus. Threatening or highly arousing task-irrelevant distractor stimuli increase
62 commission errors (De Houwer & Tibboel, 2010; Hartikainen et al., 2012), indicating that threat
63 reduced the ability to inhibit responses. This could reflect a shift in cognitive resources away
64 from the task (De Houwer & Tibboel, 2010; Hartikainen et al., 2012). No effect on Go-stimulus
65 reaction time (RT) was found that would indicate a lowered response threshold; in one study, a
66 reversed effect was found (Brown et al., 2015). This is surprising, as it contradicts the theory-
67 based expectation that threat-induced commission errors should be caused by the shift towards
68 speed versus accuracy discussed above, i.e., reducing the evidence required for response
69 execution (Krypotos, Beckers, Kindt, & Wagenmakers, 2015). This is an issue either for the
70 theory or for this method of measuring impulsivity.

71 The aim of the current paper is to address this issue, by exploring potentially important task
72 factors in the Go-Nogo task. In Study 1, the effect of task-relevance of emotional distractors was
73 tested. Previous work has shown that emotional stimuli have stronger effects when they must be
74 processed to perform the task, in terms of behavioural effects (Lichtenstein-Vidne, Henik, &
75 Safadi, 2012; Spruyt, De Houwer, & Hermans, 2009; Spruyt, Tibboel, De Schryver, & De
76 Houwer, 2018) and neural responses (Pessoa, McKenna, Gutierrez, & Ungerleider, 2002). The
77 automatic processes involved in emotional distraction may thus require at least some attention or
78 goal-relevance to be evoked, even though the subsequent effects on performance would not be
79 voluntary (Bargh, 1994; Bargh & Ferguson, 2000; De Houwer, Teige-Mocigemba, Spruyt, &
80 Moors, 2009). To extend this work to the Go-Nogo task, two versions of an emotional Go-Nogo
81 task were used. In one version, the emotional stimulus was a task-irrelevant distractor: Go versus

82 Nogo responses were signaled by probe stimuli independent from the emotional content. In the
83 other version, the emotional stimulus was the task-relevant probe stimulus: participants had to
84 perform Go versus Nogo responses based on the emotional content of the stimuli (Megías,
85 Gutiérrez-Cobo, Gómez-Leal, Cabello, & Fernández-Berrocal, 2017). This allowed us to test
86 whether task-relevant emotional, in this case threatening, stimuli would be more able to induce
87 the theoretically expected threat-enhanced impulsivity: more commission errors and lower Go-
88 RTs.

89 In Study 2, a further novel manipulation was introduced, namely the virtual relative proximity of
90 the stimuli. Proximity plays a central role in defensive responses (Blanchard et al., 2001;
91 Blanchard, Blanchard, & Griebel, 2005; Blanchard, Griebel, Pobbe, & Blanchard, 2011; Bradley,
92 2009; Kozłowska, Walker, McLean, & Carrive, 2015; Mobbs et al., 2007). The change in
93 defensive responses as a threat, e.g., a predator, comes closer is termed the defensive cascade: as
94 a threat draws physically nearer, responses shift from freeze to flight to fight (Blanchard et al.,
95 2005). At long distances, movement is suppressed (Bracha, 2004; Fanselow, 1986; Gladwin,
96 Hashemi, van Ast, & Roelofs, 2016; Roelofs, 2017; Sagliano, Cappuccio, Trojano, & Conson,
97 2014); as the threat comes closer, flight responses occurs; and at very close range, fight
98 responses are activated. Associated neurocognitive changes occur with increasing proximity to
99 threat (Mobbs et al., 2007). The defensive cascade would appear to be related to the concept of
100 defensive space, the minimal distance people desire to maintain between themselves and other
101 people and potential threats, i.e., before defensive responses are activated (Graziano & Cooke,
102 2006; Hayduk, 1983). Exposure to aggression (Vagnoni, Lewis, Tajadura-Jiménez, & Cardini,
103 2018), anxiety (de Vignemont & Iannetti, 2015; Sambo & Iannetti, 2013) and psychoticism
104 (McGurk, Davis, & Grehan, 1981) have been shown to be related to a larger defensive space.

105 Further, in an fMRI study, veterans with anger and aggression problems showed abnormal brain
106 activation in the cuneus, a region associated with the processing of emotionally salient stimulus
107 features, when stimuli appeared closer versus further away (Heesink et al., 2017). Thus, the
108 impulsivity expected to occur when confronted with threat could interact with perceived
109 proximity. In Study 2 therefore, images were scaled to be larger or smaller to generate the
110 impression of being closer or further away from the participant, using the fundamental
111 connection between stimulus size and perceived distance (Gilinsky, 1951; McCready, 1985).
112 This is termed “zoomed-in” versus “zoomed-out” below, but we note that there was no zooming
113 animation: images were only relatively large or relatively small, within the task. Note that the
114 relative rather than absolute size of a stimulus is likely important for whether a stimulus is
115 perceived as far away or close, as the absolute size has little meaning for an on-screen emotional
116 stimulus in this context. Task-relevance was also manipulated as in Study 1. We expected that
117 stimuli appearing closer to participants would enhance threat-induced effects on impulsivity.

118 In Study 3, data are presented in which the hypotheses of Study 1 were tested again, but using a
119 within-subject design in which all participants performed both the task-relevant and task-
120 irrelevant tasks.

121 In Study 4, the same within-subject design as in Study 3 was used, but with increased
122 proportions of go versus no-go trials (90% versus 10%). In the previous studies, go and no-go
123 trials were equally likely. We note some reasons to use the 50-50 distribution, in particular for
124 the aims of the current research questions on interactions with threat stimuli. First, testing
125 whether threat-stimuli indeed induce impulsive responses does not depend on having a prepotent
126 response induced by the non-emotional manipulation of go-likelihood. Second, the 50-50
127 distribution avoids the disadvantage of a relatively small number of trials in the no-go condition.

128 Third, in the task-relevant version of the task, unequal go- and nogo-frequencies would result in
129 strongly differing block-contexts, which would be confounded with trial type; and hence, results
130 would be difficult to interpret. That is: threat-go trials only occur in threat-go blocks, in which
131 participants would be exposed to primarily threatening stimuli; while on threat-nogo blocks,
132 most stimuli would be non-threatening. Fourth, unequal go and nogo distributions have the
133 disadvantage of confounding the nogo-manipulation with frequency and hence processes such as
134 expectation or attention, which could also conceivably interact with emotional stimuli. Finally, it
135 is not necessarily methodologically optimal to have a higher baseline level of impulsivity
136 induced by go-frequency; this could for example lead to ceiling effects on commission errors and
137 reduce the ability to detect additional emotional effects. However, Go-Nogo studies have tended
138 to use increased proportions of go-trials to the aim of increasing response tendency, and the final
139 Study may provide a possibly informative closer comparison to the existing literature.

140 **Study 1**

141 **2. Method**

142 **2.1. Participants**

143 Healthy participants were recruited and received study credits or a monetary reward for
144 completing the study. Participants gave informed consent. The study was approved by the ethics
145 review board. An analytical sample of 135 participants (88 female, 47 male, 23 years, $SD = 7.1$)
146 completed the experiment with performance indicating at least minimal task engagement,
147 quantified as accuracy over .5 in all analyzed trial types, excluding, for instance, participants
148 who simply executed go responses without paying attention ($n = 2$ participants were removed
149 who did not reach the criterion).

150 **2.2. Emotional Go/Nogo Task (emoGNG)**

151 The emoGNG tasks were programmed using HTML5, JavaScript and PHP. Randomization used
152 the seedrandom script by David Bau (<https://github.com/davidbau/seedrandom>). For each
153 participant, the identifier assigned to them by the participant-pool system was converted to the
154 numerical random-seed for the module. Software is available on request by emailing the
155 communicating author. We acknowledge that a general limitation of online studies is some loss
156 of control relative to a laboratory setting; however, online studies have been shown to be a valid
157 method for psychological tasks (Chetverikov & Upravitelev, 2016; van Ballegooijen, Riper,
158 Cuijpers, van Oppen, & Smit, 2016).

159 Although precise visual angles were unknown due to participants not performing the task under
160 controlled oratory conditions, e.g., using different screen sizes and sitting at different distances to
161 the screen, were estimated to subtend roughly 7.5 degrees visual angle. Text stimuli had a visual
162 angle of around 0.5 degrees. 14 pairs (neutral and angry) of computer-generated male faces were
163 used from the Bochum Emotional Stimulus Set, BESST (Thoma, Soria Bauser, & Suchan, 2013).

164 The task consisted of 10 blocks of 48 trials (see Figure 1 for an illustration). Each participant
165 performed one of two versions, with either task-relevant or task-irrelevant emotional stimuli. In
166 both versions, trials began with a white fixation cross, for 250, 300, or 350 ms. Subsequently, a
167 stimulus was presented consisting of an angry or neutral face stimulus and a small *x* or *o* symbol,
168 placed at a random location on the face. In the Task-Relevant version, participants were
169 instructed either to press space when an angry face appeared and to do nothing when a neutral
170 face appeared; or to press space when a neutral face appeared and to do nothing when an angry
171 face appeared. In the Task-Irrelevant version, participants were instructed either to press space
172 when an *x* appeared and to do nothing when an *o* appeared; or to press space when an *o* appeared

173 and to do nothing when an x appeared. In both conditions, the Go/Nogo mapping instructions
174 alternated per block. Participants had 600 ms to respond before the stimuli disappeared.
175 Feedback was presented after incorrect responses for 400 ms: A red “Incorrect!”, or a red “Too
176 late!”

177 <Figure 1>

178

179 Go and Nogo trials were presented with equal probability. Although previous Go-Nogo tasks
180 have often used lower probabilities for Nogo stimuli with the aim of increasing response
181 likelihood and hence the probability of commission errors, please note that equal probabilities do
182 not threaten evidence for threat-induced impulsivity (and the results will indeed show that
183 relatively infrequent Nogo trials are not necessary to find such effects). A further advantage of
184 equal probabilities is that there is no confound between stimulus type and frequency.

185 **2.3. Procedure**

186 Inclusion proceeded via an online participant-pool system. Participants could sign up for the
187 study based on a brief description, after which they could read the extensive information and
188 decide whether to continue. Participants performed one of the emoGNG versions selected at
189 random. Other questionnaires and tasks were performed in the same session that were related to
190 other studies.

191 **2.4. Preprocessing and Statistical Analyses**

192 The first block of the task, the first four trials per block and trials following errors were removed
193 as these were considered to potentially deviate from normal task performance. Analyses were
194 performed in order to test effects per task as well as to compare the effects between tasks. Effects
195 per task were tested with a repeated measures ANOVA. The analyses were performed with the

196 dependent variables median RT, and the asin-square transformation of mean accuracy scores;
197 these measures were decided on prior to observing statistical results. Median RTs were used to
198 avoid effects of outliers which would require arbitrary cut-offs using the mean. The
199 transformation of the mean accuracy scores was used to normalize the distribution. For RT, only
200 go trials were included in the analysis. The within-subject factor was Threat (Angry face versus
201 Neutral face). For accuracy, the within-subject factors were Threat and Go/Nogo (Go versus
202 Nogo). In a subsequent mixed design ANOVA, task version was used as an additional between-
203 subject variable to test interactions involving task version. Note that we chose to present the
204 results for each task separately, to prevent the presentation of information per task depend on the
205 binary outcome of interactions involving the task version. Effects are reported if they reach
206 nominal significance, with for tests of interest (see below) an asterisk added if they reach
207 significance with Bonferroni correction for the number of tests of interest in the study; we note
208 that the issue of deciding for which set of tests for which to correct is non-trivial, but believe the
209 number of tests of interest provide a balanced choice. For this study, these tests were the effects
210 involving threat: the effect of threat for RT, and the effect of threat and the threat x go interaction
211 for accuracy. As these tests were performed per task version separately and there were tests of
212 the interaction of each effect with task version, there were nine tests of interest and the critical p -
213 value was $.05/9 = .0056$. For the smaller number of participants per task version ($n = 66$), for a
214 medium effect size, the power for uncorrected tests was .98 and for corrected tests .88, using
215 GPower (Faul, Erdfelder, Lang, & Buchner, 2007) All data and scripts are available at the Open
216 Science Framework, <https://osf.io/6gmrj/>.

217 3. Results

218 66 participants performed the task-irrelevant emoGNG, and 69 participants performed the task-
219 relevant emoGNG. Descriptive statistics are presented in Table 1.

220

221 Table 1. RT and accuracy on the emoGNG

222 1A. Reaction time on Go trials

Task version	Emotion	RT (SD)
Task-irrelevant	Neutral	449 (29)
	Angry	450 (31)
Task-relevant	Neutral	428 (33)
	Angry	419 (30)

223

224 1B. Accuracy

Task version	Emotion	Go/Nogo	Accuracy
Task-irrelevant	Neutral	Nogo	.93
		Go	.94
	Angry	Nogo	.92
		Go	.94
Task-relevant	Neutral	Nogo	.91
		Go	.92
	Angry	Nogo	.88
		Go	.93

225

226 *Note.* Mean and standard deviation of reaction time in ms and mean accuracy in proportion correct per
227 condition of the emoGNG over participants. Task version refers to task-relevance of the emotional
228 expression of the faces (Neutral or Angry).

229

230 3.1. Task-Irrelevant emoGNG

231 There was no effect of Threat on RT ($p = .48$) and no interaction between Go/Nogo and Threat
232 on accuracy ($p = .092$). Go trials were more accurate than Nogo trials, $F(1, 65) = 11, p = .0013,$
233 $\eta_p^2 = 0.15$ (.94 versus .92).

234 **3.2. Task-Relevant emoGNG**

235 On RT, there was an effect of Threat, $F(1, 68) = 15, p = .00027 *$, $\eta_p^2 = 0.18$, responding to

236 Angry faces being faster than responding to Neutral faces (419 ms versus 428 ms).

237 On accuracy, there was an interaction between Go/Nogo and Threat, $F(1, 68) = 21, p < .0001 *$,

238 $\eta_p^2 = 0.24$. This was due to lower accuracy for Angry than Neutral faces on Nogo trials, $F(1, 68)$

239 $= 19, p < .0001 *$, $\eta_p^2 = 0.22$ (.88 versus .91 proportion correct), and higher accuracy for Angry

240 than Neutral faces on Go trials, $F(1, 68) = 19, p = .044, \eta_p^2 = 0.058$ (.93 versus .92). Further, Go

241 trials were more accurate than Nogo trials, $F(1, 68) = 20, p < .0001, \eta_p^2 = 0.22$ (.92 versus .90).

242 **3.3. Between-Task Comparisons**

243 The above difference in effects between the tasks were formally tested using a mixed design

244 ANOVA. On RT, the interaction between Task version and Threat was significant, $F(1, 133) =$

245 $13, p = .00052, \eta_p^2 = 0.087$. No task-related interaction reached significant on accuracy, although

246 the Task x Go/Nogo x Threat interaction was close ($p = .056$).

247 **4. Discussion**

248 The aims of Study 1 were to provide further information on whether threatening social stimuli

249 induce impulsivity and determine what the effect is of using a task in which the emotional cues

250 are task-relevant versus task-irrelevant. Effects involving threat were only found for the Task-

251 Relevant version. Most importantly, a speeding effect was found on RTs on go trials. Using task-

252 irrelevant emotional cues or distractors was also not previously found to affect RT on go-trials

253 (De Houwer & Tibboel, 2010; Hartikainen et al., 2012). Making the emotional stimuli task-

254 relevant appeared to allow them to induce impulsivity as detected via speeding, similarly to

255 effects of task-relevance in other emotional tasks (Lichtenstein-Vidne et al., 2012; Spruyt et al.,

256 2009, 2018).

257 **Study 2**

258 Study 2 concerned an additional manipulation aiming to manipulate perceived proximity of the
259 threatening and neutral stimuli.

260 **2. Method**

261 **2.1. Participants**

262 Healthy participants were recruited and received study credits or a monetary reward for
263 completing the study, which was performed fully online. Participants gave informed consent and
264 the study was approved by the local ethics review board. 173 participants (151 female, 22 male;
265 mean age 20, $SD = 3.3$) completed the experiment with performance indicating at least minimal
266 task engagement, quantified as accuracy over .5 in all analyzed trial types ($n = 2$ participants
267 were removed).

268 **2.2. Proximity version of the Emotional Go/Nogo Task (proxemoGNG)**

269 The proxemoGNG consisted of 9 blocks of 40 trials. Trials were identical to those of the
270 emoGNG, with the exception of a random “zoom-in” effect that occurred with 0.5 probability on
271 all trials. Note for clarity the zoom did not involve a movement animation: stimuli were simply
272 presented at different sizes. The facial visual stimuli subtended around 7.5 degrees visual angle,
273 except when zoomed-in in which case the angle was 15 degrees (as above, the precise visual
274 angles will have varied somewhat). The proxemoGNG was also presented in either a Task-
275 Relevant and Task-Irrelevant version.

276 **2.3. Procedure**

277 Inclusion proceeded via an online participant-pool system. Participants could sign up for the
278 study based on a brief description, after which they could read the extensive information and

279 decide whether to continue. Participants performed the Task-Relevant or the Task-Irrelevant
280 version of the proxemoGNG, selected at random.

281 **2.4. Preprocessing and Statistical Analyses**

282 The first block of the task, the first four trials per block, and trials following errors were
283 removed. Analyses were performed in order to test effects per task as well as to compare the
284 effects between tasks. Effects per task were tested with a repeated measures ANOVA. The
285 analyses were performed with the dependent variables median RT and the asin-square
286 transformation of accuracy scores. For RT, only go trials were included in the analysis. The
287 within-subject factors were Proximity (Zoomed-In versus Zoomed-Out) and Threat (Angry face
288 versus Neutral face). For accuracy, the within-subject factors were Proximity, Threat and
289 Go/Nogo (Go versus Nogo). The effects of interest were now all those involving Proximity and
290 Threat, so for RT the effect of Proximity, the effect of Threat, and their interaction; and for
291 accuracy, the effect of Proximity, the effect of Threat, their interaction with each other and with
292 Go, and the three-way interaction. These effects were of interest for the separate task versions
293 and for the interaction between task versions, leading to $9 \times 3 = 27$ tests of interest and a critical
294 p -value of .0019. For the smaller number of participants per task version ($n = 84$), for a medium
295 effect size ($d = .5$), the power for uncorrected tests was .99 and for corrected tests .91. Effect size
296 was calculated for a two-sided paired-sample t -test, representing the contrast for a main effect or
297 interaction with a single degree of freedom (as was the case for all effects in the current studies).
298 In a subsequent mixed design ANOVA, task version was used as a between-subject variable to
299 test interactions involving task version.

300 **3. Results**

301 89 participants performed the task-irrelevant proxemoGNG, and 84 participants performed the

302 task-relevant proxemoGNG. Descriptive statistics are presented in Table 2.

303

304 Table 2. RT and accuracy on the proxemoGNG

305 2A. RT on Go trials

Task version	Emotion	Proximity	RT (SD)
Task-irrelevant	Neutral	Far	457 (31)
		Near	453 (32)
	Angry	Far	457 (32)
		Near	452 (31)
Task-relevant	Neutral	Far	434 (37)
		Near	433 (36)
	Angry	Far	436 (37)
		Near	413 (37)

306

307 2B. Accuracy

Task version	Emotion	Go/Nogo	Proximity	Accuracy
Task-irrelevant	Neutral	Nogo	Far	.94
			Near	.94
		Go	Far	.94
			Near	.95
	Angry	Nogo	Far	.93
			Near	.93
		Go	Far	.94
			Near	.95
Task-relevant	Neutral	Nogo	Far	.93
			Near	.91
		Go	Far	.91
			Near	.92
	Angry	Nogo	Far	.86
			Near	.91
		Go	Far	.92
			Near	.94

308

309 *Note.* Mean and standard deviation of reaction time in ms and mean accuracy in proportion correct per
 310 condition of the proxemoGNG over participants. Task version refers to task-relevance of the emotional
 311 expression of the faces (Neutral or Angry). Proximity refers to whether the face presented on the trial
 312 was zoomed in (Near) or not (Far).

313 **3.1. Task-Irrelevant proxemoGNG**

314 On RT, the only significant effect was of Proximity, $F(1, 88) = 9.9, p = .0022, \eta_p^2 = 0.10,$
 315 zoomed-in stimuli evoking a faster response than zoomed-out stimuli (453 ms versus 457 ms).
 316 On accuracy, the only effect was of Go/Nogo, $F(1, 88) = 7.7, p = 0.0069, \eta_p^2 = 0.080,$ Go-
 317 responses being more accurate than Nogo-responses (.95 versus .94).

318 **3.2. Task-Relevant proxemoGNG**

319 On RT, effects were found of Threat, $F(1, 83) = 30, p < .0001 *, \eta_p^2 = 0.26,$ Angry faces evoking
 320 faster responses than Neutral faces (424 ms versus 433 ms); Proximity, $F(1, 83) = 54, p < .0001$
 321 $*, \eta_p^2 = 0.39,$ zoomed-in stimuli evoking a faster response than zoomed-out stimuli (423 ms
 322 versus 435 ms); and, essentially for the research question, the Proximity x Threat interaction,
 323 $F(1, 83) = 63, p < .0001 *, \eta_p^2 = 0.43,$ due to the effect of Threat only being significant for the
 324 zoomed-in stimuli, $F(1, 83) = 100, p < .0001 *, \eta_p^2 = 0.55$ (413 ms versus 433 ms).

325 On accuracy, effects were found of Go/Nogo, $F(1, 83) = 7.8, p = .0064, \eta_p^2 = 0.086,$ Go
 326 responses being more accurate than Nogo responses (.92 versus .90); Proximity, $F(1, 83) = 18, p$
 327 $< .0001 *, \eta_p^2 = 0.17,$ responses to zoomed-in stimuli being more accurate than responses to
 328 zoomed-out stimuli (.92 versus .91); Go/Nogo x Threat, $F(1, 83) = 35, p < .0001 *, \eta_p^2 = 0.30,$
 329 due to the effect of Go being significant only for Threat stimuli, $F(1, 83) = 26, p < .0001 *, \eta_p^2 =$
 330 $0.24;$ Proximity x Threat, $F(1, 83) = 32, p < .0001 *, \eta_p^2 = 0.28,$ the effect of Angry versus
 331 Neutral faces reversing for zoomed-out (lower accuracy for Angry faces, .89 versus .92) versus
 332 zoomed-in faces (higher accuracy for Angry faces, .93 versus .92); and Go/Nogo x Proximity x
 333 Threat, $F(1, 83) = 7.5, p = .0075, \eta_p^2 = 0.083.$ For zoomed-out faces, there was a Go/Nogo x
 334 Threat interaction, $F(1, 83) = 40, p < .0001 *, \eta_p^2 = 0.32,$ due to an effect of Threat for Nogo
 335 trials only, with more commission errors for Angry faces. For zoomed-in faces, there was also a

336 Go/Nogo x Threat interaction, $F(1, 83) = 8.1, p = .0056, \eta_p^2 = 0.089$, due to higher accuracy for
 337 Angry than Neutral faces for Go trials only.

338 **3.3. Between-Task Comparisons**

339 The above descriptive differences between task versions were tested using the mixed design
 340 ANOVA. On RT, the following interactions were found, all due to the within-subject effect
 341 being stronger in the Task-Relevant task version than in the Task-Irrelevant task version: Task
 342 version x Threat, $F(1, 171) = 15, p = .00012^*, \eta_p^2 = 0.083$; Task version x Proximity, $F(1, 171)$
 343 $= 9.9, p = .0020, \eta_p^2 = 0.055$; Task-Version x Proximity x Threat, $F(1, 171) = 30, p < .0001^*$,
 344 $\eta_p^2 = 0.15$.

345 On accuracy, the following interaction effects were found, all due to the within-subject effect
 346 being significant only for the Task-Relevant task version: Task-Version x Go/Nogo x Threat,
 347 $F(1, 171) = 11, p = .00092^*, \eta_p^2 = 0.062$; Task-Version x Proximity x Threat, $F(1, 171) = 17, p$
 348 $= .00053^*, \eta_p^2 = 0.091$; Task-Version x Go/Nogo x Proximity x Threat, $F(1, 171) = 6.2, p$
 349 $= .014, \eta_p^2 = 0.035$.

350 **4. Discussion**

351 The aims of the Study 2 were to test the effect of virtual stimulus proximity. The results also
 352 allowed a conceptual replication of the task-relevance effect on impulsivity found in Study 1.
 353 Threat-effects were again only found in the task-relevant version. Proximity was found to be
 354 related to enhanced effects of threat on impulsivity, but only for the Task-Relevant task version
 355 and most clearly for RT. This proximity effect for RT is in line with the defensive cascade
 356 (Blanchard et al., 2001, 2005; Bradley, 2009; Heesink et al., 2017; Mobbs et al., 2007), in which
 357 defensive responses depend on the distance to the threat. A threat appearing close by naturally
 358 requires faster responses to escape, as an attack at shorter distance leaves less time to respond. It

359 would therefore be expected that proximity would enhance threat-induced impulsivity, as
360 suggested by the RT results. Although an interaction was also found for accuracy, the pattern of
361 these results was more difficult to interpret. The expected increase in commission errors for
362 angry versus neutral faces was found for distant rather than nearby stimuli; while, more in line
363 with expectations, for nearby stimuli fewer false negatives were found for angry versus neutral
364 faces. One post-hoc interpretation of this phenomenon could be that the nearby presentation of
365 faces has an effect of enhancing attentional engagement and thereby improving accuracy, but
366 clearly this must be considered only speculative.

367 **Study 3**

368 Study 3, as Study 1, concerned a task-relevant and task-irrelevant version of an emotional Go-
369 Nogo task. However, Study 3 used a within-subject design.

370 **2. Method**

371 **2.1. Participants**

372 Healthy adult participants were recruited and received study credits for completing the study.
373 Participants gave informed consent. The study was approved by the ethics review board. 95
374 participants completed the experiment (79 female, 16 male; 21 years, $SD = 2.7$) with accuracy
375 above .5 on all conditions ($n = 6$ participants were removed).

376 **2.2. Emotional Go/Nogo Task (emoGNG)**

377 The same tasks as in Study 1 were used. The number of blocks per task was 5, and the number of
378 trials per block were 24.

379 **2.3. Procedure**

380 Inclusion proceeded via an online participant-pool system. Participants could sign up for the
381 study based on a brief description, after which they could read the extensive information and

382 decide whether to continue. Participants performed both of the emoGNG versions, in random
383 order. Other questionnaires and tasks were performed in the same session that were related to
384 other studies.

385 **2.4. Preprocessing and Statistical Analyses**

386 Preprocessing and analyses were the same as in Study 1, with the exception of task version now
387 being a within-subject variable. The corrected p -value was .0056 as in Study 1. For a medium
388 effect size, the power for uncorrected tests was 1.00 and for corrected tests .98.

389 **3. Results**

390 Descriptive statistics are presented in Table 3.

391

392 Table 3. RT and accuracy on the emoGNG, within-subject design

393 3A. Reaction time on Go trials

Task version	Emotion	RT (SD)
Task-irrelevant	Neutral	450 (29)
	Angry	452 (28)
Task-relevant	Neutral	423 (30)
	Angry	417 (31)

394

395 3B. Accuracy

Task version	Emotion	Go/Nogo	Accuracy
Task-irrelevant	Neutral	Nogo	.93
		Go	.95
	Angry	Nogo	.91
		Go	.95
Task-relevant	Neutral	Nogo	.90
		Go	.92
	Angry	Nogo	.87
		Go	.93

396

397 *Note.* Mean and standard deviation of reaction time in ms and mean accuracy in proportion correct per
 398 condition of the emoGNG over participants. Task version refers to task-relevance of the emotional
 399 expression of the faces (Neutral or Angry).

400

401 **3.1. Task-Irrelevant emoGNG**

402 There was no effect of Threat on RT and no interaction between Go/Nogo and Threat on
 403 accuracy ($p = .11$). Go trials were more accurate than Nogo trials, $F(1, 94) = 30, p < .0001, \eta_p^2 =$
 404 0.24 (.95 versus .92). Angry trials were less accurate than Neutral trials, $F(1, 94) = 5.5, p =$
 405 $0.021, \eta_p^2 = 0.056$ (.93 versus .94).

406 **3.2. Task-Relevant emoGNG**

407 On RT, there was an effect of Threat, $F(1, 94) = 9, p = .0035 *$, $\eta_p^2 = 0.087$, responding to Angry
 408 faces being faster than responding to Neutral faces (417 ms versus 423 ms).

409 On accuracy, there was an interaction between Go/Nogo and Threat, $F(1, 94) = 14, p = .0003 *$,
 410 $\eta_p^2 = 0.13$. This was due to lower accuracy for Angry than Neutral faces on Nogo trials, $F(1, 94)$
 411 $= 10, p = .00017 *$, $\eta_p^2 = 0.099$ (.92 versus .93 proportion correct), but higher accuracy on Go
 412 trials, $F(1, 94) = 4.6, p = .034, \eta_p^2 = 0.047$ (.93 versus .92 proportion correct). Further, Go trials
 413 were more accurate than Nogo trials, $F(1, 94) = 31, p < .0001, \eta_p^2 = 0.25$ (.93 versus .89).

414 **3.3. Between-Task Comparisons**

415 The above difference in effects between the tasks were formally tested using a repeated measures
 416 ANOVA. On RT, the interaction between Task version and Threat was significant, $F(1, 94) =$
 417 $14, p = .00027 *$, $\eta_p^2 = 0.13$. On accuracy, the interaction between Task version, Go/Nogo, and
 418 Threat was significant, $F(1, 94) = 4.9, p = .029, \eta_p^2 = 0.05$.

419 **4. Discussion**

420 The results replicated the main pattern of effects from Study 1, but in a within-subject rather than
 421 between-subject design. Again, only in the task-relevant task version were threat stimuli
 422 associated with faster responses. Further, the Threat x Go interaction was only found in the task-

423 relevant version. The results of Study 3 thus provide an important bridge to Study 4, in which
424 90-10 Go-Nogo proportions were used in a within-subject design.

425 **Study 4**

426 Study 4 was similar to Study 3, but used a 90% versus 10% percentage of go versus stop trials.

427 **2. Method**

428 **2.1. Participants**

429 Healthy adult participants were recruited and received study credits for completing the study.

430 Participants gave informed consent. The study was approved by the ethics review board. 46

431 participants completed the experiment (40 female, 6 male, 21 years, $SD = 6.2$), with a minimum

432 accuracy of .1 in all conditions. The minimum accuracy criterion used in previous studies (with

433 equal go and nogo frequencies) was found to be too strict in this task variant, leading to rejection

434 of the majority of participants. This was due to a large increase in the rate of commission errors.

435 The more lenient criterion was used in order to attempt to restrict removal to participants who

436 were most likely failing to try to inhibit responses at all ($n = 6$).

437 **2.2. Emotional Go/Nogo Task (emoGNG)**

438 The same tasks as in Study 3 were used, but with a 90% go, 10% nogo rate. For each task

439 version, there was a practice task with 2 blocks of 24 trials. The full assessment versions of the

440 tasks had 10 blocks of 24 trials.

441 **2.3. Procedure**

442 Inclusion proceeded via an online participant-pool system. Participants could sign up for the

443 study based on a brief description, after which they could read the extensive information and

444 decide whether to continue. Participants performed short practice versions of both emoGNG

445 versions, and then assessment versions of both emoGNG versions, with the order of task-
446 relevance randomized per participant.

447 **2.4. Preprocessing and Statistical Analyses**

448 The preprocessing and analyses were identical to Study 3. Only the assessment versions were
449 used for analysis. The corrected p-value remained .0056. Given the large effects in previous
450 studies, power was calculated for large effect sizes ($d = .8$): the power for uncorrected tests was
451 1.00 and for corrected tests .99. For medium effect size, power would be .91 for uncorrected
452 and .68 for corrected tests.

453 **3. Results**

454 Descriptive statistics are presented in Table 4.

455

456 Table 4. RT and accuracy on the emoGNG, 90-10 go-nogo rates version

457 4A. Reaction time on Go trials

Task version	Emotion	RT (SD)
Task-irrelevant	Neutral	416 (39)
	Angry	417 (38)
Task-relevant	Neutral	361 (45)
	Angry	362 (43)

458

459 4B. Accuracy

Task version	Emotion	Go/Nogo	Accuracy
Task-irrelevant	Neutral	Nogo	.56
		Go	.97
	Angry	Nogo	.55
		Go	.97
Task-relevant	Neutral	Nogo	.52
		Go	.97
	Angry	Nogo	.53
		Go	.96

460

461 *Note.* Mean and standard deviation of reaction time in ms and mean accuracy in proportion correct per
 462 condition of the emoGNG over participants. Task version refers to task-relevance of the emotional
 463 expression of the faces (Neutral or Angry).

464

465 **3.1. Task-Irrelevant emoGNG**

466 There was no effect of Threat on RT ($p = .093$, direction of effect in reversed direction) and no
467 interaction between Go/Nogo and Threat on accuracy ($p = .86$). Go trials were more accurate
468 than Nogo trials, $F(1, 45) = 520$, $p < 0.0001$, $\eta_p^2 = 0.92$ (.97 versus .56).

469 **3.2. Task-Relevant emoGNG**

470 There was no effect of Threat on RT ($p = .76$) and no interaction between Go/Nogo and Threat
471 on accuracy ($p = .12$). Go trials were more accurate than Nogo trials, $F(1, 45) = 400$, $p < 0.0001$,
472 $\eta_p^2 = 0.90$ (.97 versus .53).

473 **3.3. Between-Task Comparisons**

474 There were no interactions involving task version.

475 **4. Discussion**

476 With 90-10 rates of go and nogo trials, there was no sign of the threat-related effects found in
477 previous studies. This was the case for both the task-relevant and task-irrelevant version. We
478 reiterate one of the reasons for using equal versus unequal rates: the block-context strongly
479 differs when Threat is mapped to go versus nogo responses (e.g., the frequency of Angry versus
480 Neutral faces changes along with the current block's task instructions), which may well interact
481 with effects of trial type. While there are clearly many possible variations involving go - nogo
482 rates, the current study's rationale and results would appear to suggest that using 50-50 rates
483 should be considered a potentially interesting and valid design choice. The consistent threat-
484 related results found for the task-relevant version with 50-50 rates were lost with the 90-10 rates,
485 and there is no indication that this change revealed threat-related effects that were absent in the
486 previous task-irrelevant versions.

487 **5. General Discussion**

488 The current studies aimed to determine whether threat induces impulsivity as reflected in both
489 speeding and commission errors on a Go-Nogo task. A number of task design choices were
490 explored. As discussed in the introduction, there were various reasons to choose equal rates for
491 go and nogo frequencies, and the null results of Study 4, which used 90-10 rates in contrast with
492 the other three studies, suggest that the 50-50 design is more sensitive to threat effects. In the
493 first three studies, but only in the task-relevant versions, the presence of angry faces caused
494 faster responses and more commission errors. This is in line with a reduction in response
495 threshold induced by threatening stimuli, as would be expected from their evolutionary
496 significance. No significant effects involving threat-induced impulsivity were found in the task-
497 irrelevant versions. It may be the case that the automatic bias due to threatening stimuli only
498 induces impulsivity when the inducing stimuli are task-relevant, as has been found in previous
499 work, with various broadly related conceptualizations of task-relevance (Lichtenstein-Vidne et
500 al., 2012; Spruyt et al., 2009, 2018). Note that this does not entail a “non-automatic” effect -
501 participants were not instructed to respond faster to Threat stimuli, but this occurred
502 automatically when they had to process emotional information to perform the task. It may also be
503 the case that when distractors were task-irrelevant, the effect of the facial expression was muted
504 via selective attention. The ability to suppress, or treat as irrelevant, potentially distracting
505 emotional information has been speculated to play a conceptually similar role in various effects
506 related to attentional biases (Gladwin, 2017; Gladwin, Ter Mors-Schulte, Ridderinkhof, & Wiers,
507 2013). In this case, the ability to tune out task-irrelevant, potentially distracting information
508 could reduce threat-evoked effects on task-irrelevant Go-Nogo tasks.

509 The impact of having the threatening stimuli appear to have closer proximity was as predicted
510 for reaction times, although, again, effects required task-relevant stimuli. Although effects on
511 accuracy were more difficult to interpret, relative proximity increased threat-induced speeding.
512 This was expected given the view of a natural, evolutionarily preserved tendency to respond
513 quickly, and hence with less extensive evaluation of response selection, to nearby threatening
514 stimuli (Blanchard et al., 2001, 2005; Bradley, 2009). Proximal threat evokes
515 psychophysiological activity related to acute emotional-physiological responses to threat (Löw,
516 Lang, Smith, & Bradley, 2008; Mobbs et al., 2007). In line with this, neuroimaging results from
517 the Fear and Escape Task (Montoya, Terburg, Bos, & van Honk, 2012) in a population of
518 veterans indicate that abnormal reactions to proximity may be involved in anger and aggression
519 problems (Heesink et al., 2017). A “looming” stimulus (Vagnoni, Lourenco, & Longo, 2012)
520 was found to evoke abnormally strong activation in attention-related brain regions in participants
521 with anger and aggression problems. It would appear that anger disorders are a particularly
522 worthwhile clinical focus of further study of proximity-enhanced, threat-induced speeding.

523 The current study had a number of limitations. First, a sample of students was used for pragmatic
524 reasons, rather than, e.g., potentially interesting clinical or forensic groups. It is possible that
525 different effects would be found in groups with more dysfunctional responses to threat. Second,
526 the study was online, which reduces the ability to control the testing environment, e.g., as noted
527 by a reviewer, screen size, distance to screen and luminance. We do note that online studies have
528 clear practical advantages in terms of the efficiency of acquiring data and in many cases should
529 not preclude or complicate finding meaningful effects of task manipulations. A different trade-
530 off of concerns could hold in future studies, in particular using clinical populations, indicating
531 the use of laboratory settings. Third, although the results of Study 4 appear to point in a clear

532 direction supporting the use of equal probabilities in this context, it is not certain to which extent
533 the results will or will not generalize to Go/Nogo tasks with other specific proportions of nogo
534 trials. Fourth, the numbers of blocks and trials were slightly different in different studies. There
535 was no principled reason for the precise trial numbers, but this minor difference would not seem
536 to substantially affect any conclusions drawn from the studies. Fifth, the study was focused on a
537 specific stimulus type, namely faces with angry versus neutral expressions. While this was a
538 conscious feature of the study and specifically extends the literature on emotional Go/Nogo tasks
539 to these stimuli, the current results cannot say whether the differences between the Emotion-
540 Relevant and Emotion-Irrelevant task versions will generalize to different stimuli. We also
541 cannot specify the precise feature of the threatening stimuli that induced impulsivity, e.g.,
542 whether the angry faces were more arousing or more negative (note that threat itself as a concept
543 is related to both arousal and negative valence). Sixth, there were no self-report measures of the
544 perception of the faces or the proximity effect in the current study. However, self-report data
545 were available from a previously published study in which stimuli from the same set were used
546 (Gladwin, 2017). Participants at a pre-test assessment reported, on a 1 (Not at all) to 7
547 (Extremely) Likert scale, feeling more unpleasant, $t(51) = 16.68$, $d = 2.31$, $p < .001$, intimidated,
548 $t(51) = 7.46$, $d = 1.04$, $p < .001$, aggressive, $t(51) = 10.93$, $d = 1.52$, $p < .001$ and out of control,
549 $t(51) = 8.16$, $d = 1.13$, $p < .001$, when viewing the angry versus neutral faces, while there was no
550 significant difference for feeling excited, $t(51) = 0$, $d = 0$, $p = 1.00$ or ashamed, $t(51) = 1.83$, $d =$
551 0.25 , $p = .073$. Seventh, the current studies used one particular task – responding to x and o
552 stimuli superimposed on the background stimuli - in the task-irrelevant versions, and the current
553 data do not provide direct evidence results might not differ with a different task. Finally, as the
554 proximity manipulation involved a change in stimulus size, we cannot determine whether

555 perceived proximity or mere stimulus size caused effects. Future research could attempt to
556 disentangle this, e.g., by presenting a framing image of a consistent size within which a
557 foreground image varied in size to indicate its proximity. There is clearly scope for many lines of
558 future research, exploring many more variations of task design and parameters and providing
559 more precise information on which emotional stimulus features or combination of features evoke
560 impulsivity. However, the current results provide a proof of principle that at least using the
561 current stimuli and task parameters, task-relevance affects impulsivity evoked by stimuli
562 involving threat.

563 In conclusion, angry versus neutral faces are able to induce impulsive responding, but significant
564 effects were only found when these emotional stimuli were task-relevant and when go and nogo
565 trials were equally frequent. With this task version, partial support was found in RT effects for
566 the hypothesis that threat-induced impulsivity would be enhanced by increasing the perceived
567 proximity of the threatening stimulus. Future research in which effects of impulsivity on RT are
568 of interest could consider using this task design.

569 **Funding**

570 This research did not receive any specific grant from funding agencies in the public, commercial,
571 or not-for-profit sectors.

572 **Declaration of conflicting interests**

573 The Authors declare that there is no conflict of interest.
